Green Star – Design & As Built

Shared Services and Low-Carbon Energy Supply Assessment Guidelines

This guide is to be used for both credits in the Energy category: Greenhouse Gas Emissions and Peak Electricity Demand Reduction

28 April 2014

DRAFT d1

Green Star – Design & As Built Shared Services and Low-Carbon Energy Supply Assessment Guidelines DRAFT d1

Introduction

The Greenhouse Gas Emissions credit in Green Star – Design & As Built makes provision for the selection of energy supply in rewarding projects for a reduction in GHG emissions. The intent of this approach is to reward buildings which connect to low-carbon energy sources at a utility-scale, rather than only reward those projects which produce low-carbon energy on-site. This methodology is to be applied wherever the grid is used to transmit power between the source and the consumer, and also for any scenarios where energy is transferred between independent retail customers even if they are within the same building (e.g. base building and tenant).

This approach is intended to cover the procurement opportunities for district energy and utility systems including:

- District thermal networks
- Shared cogeneration or trigeneration systems
- Private wire networks with embedded renewable energy
- Renewable energy sources, including accredited GreenPower
- Grid connected low-carbon energy (e.g. biomass or biogas systems)

This approach does not include carbon offsets.

Where shared systems are intended to meet the full building load for a particular energy stream, the energy contracts must demonstrate that sufficient capacity is available.

Where shared thermal energy systems are only intended to meet a portion of the building load, the energy contracts must identify the total annual capacity which can be accessed. Any building systems required to meet the full load must be assessed in accordance with the **Building Energy**

Consumption and Greenhouse Gas Emissions Calculation Guidelines and use the applicable greenhouse gas emission factors for the energy source used; the shared service greenhouse gas emission factors apply only to the energy delivered by that service.

There is a wide variety of assessment approaches to the analysis of complex energy utility arrangements in combination with building systems. For the purposes of the Greenhouse Gas Emissions credit, projects procuring energy from alternative sources (i.e. other than or supplementary to the electricity grid and natural gas network) will calculate a project specific GHG emissions factor to be applied to the energy demand assessed for the building.

Due to the complexity of analysing shared utility systems, project teams must submit a method statement to the GBCA for review prior to implementation in the Greenhouse Gas Emissions credit calculation.

There are two approaches to assessing the GHG impact of low-carbon utilities described in this document:

- 1. Procurement Contract Approach: Identify the GHG emissions co-efficient on the Power Purchase Agreement (PPA) and/or Thermal Power Purchase Agreement (TPPA)
- 2. Design Analysis Approach: Prepare a Design Intent Report (DIR) that calculates the GHG coefficient for the project.

Green Star – Design & As Built Shared Services and Low-Carbon Energy Supply Assessment Guidelines

DRAFT d1

1. Procurement Contract Approach

Applicable to projects seeking to be rewarded based on the disclosure of the carbon intensity nominated within an energy procurement contract. GHG emission coefficients must be individually disclosed within the PPA and TPPA documentation for each of the following, as applicable to the project:

- Electricity
- Chilled water
- Heating Hot Water
- Domestic hot water.

These GHG emissions coefficients must be applied to the corresponding energy demand in the Green Star – Design & As Built Energy Calculator.

2. Design Analysis Approach

Projects that do not have GHG Emissions Coefficients embedded within their procurement documentation must undertake a detailed analysis of the shared utility to calculate the GHG factors for their project.

The documentation of the GHG Emissions analysis must be shown in three distinct steps:

- Step 1: Define the shared utility system
- Step 2: Calculate the carbon emissions coefficient for utility services
- Step 3: Apply the overall GHG Emissions Factors to the targeted demand-side energy in the Energy Calculator

Defining the Utility System

The proposed low-carbon utility must be clearly defined in terms of its:

- Component parts (e.g. chillers, boilers, cogeneration engines, renewable energy systems, generators, thermal storage systems etc)
- Inputs (e.g. fuel, grid electricity etc)
- Outputs (e.g. electricity, chilled water, hot water)
- Total connected load (or the 'design load')

The GHG emissions performance of cogeneration systems in particular is highly sensitive to the intended operating profile. Any utility systems being assessed in this manner must be modelled on the basis of their intended actual operation. The operational profile must be embedded within the energy supply contracts as it is material to the GHG performance of the energy supply.

Furthermore, the contractual parties relevant to the energy procurement must be identified. At a minimum, this must include the energy retailer and the building owner.

Calculating GHG Emissions

The calculation of the overall energy performance of complex shared utilities requires detailed system modelling of the full utility system; including those elements outside the boundary of the building under assessment. The proposed utility system must be assessed using utility system modelling software (such as energyPRO (<u>http://www.emd.dk/energypro/frontpage</u>)) to assess the overall performance of the central utility.

Where detailed connection information beyond the building boundary is not known, an assessment of future connected load is required. This assessment should include a plausible development profile (with evidence from zoning or development plan documentation), building load profiles (default to minimum code compliant buildings if no other requirements are documented in local regulations) and

Green Star – Design & As Built

Shared Services and Low-Carbon Energy Supply Assessment Guidelines

DRAFT d1

occupancy profiles (on the basis of the primary use of the buildings). Calculations must include allowances for losses from and gains to thermal energy distribution systems.

The outputs of the system modelling must include (as applicable to the project):

- Total annual electricity produced
- Total annual chilled water generated
- Total annual heating hot water generated
- Total annual domestic hot water generated
- Total annual GHG emissions

For each system, the total annual GHG emissions attributable to the system must be calculated (based on the fuel and energy inputs) and attributed evenly to the total annual energy stream that it produces:

- For electricity kgCO_{2e} /kWh_{electricity}
- For chilled water kgCO_{2e} /MJ_{thermal}
- For heating hot water kgCO_{2e} /MJ_{thermal}
- For domestic hot water kgCO_{2e} /MJ_{thermal}

Where a single process produces multiple energy streams, the total emissions must be apportioned on the basis of the proportion of primary energy used to generate them with any waste heat elements split equally between the energy streams.

Where the shared utility does not meet 100% of the energy requirements of the building, grid energy should be used for any unmet demand. A blended GHG emissions factor should be calculated based on the proportion of demand met from each source. The final GHG emissions factors should reflect the overall, blended emissions factors for each energy stream.

The Energy Efficiency Council is preparing an Emissions Allocation Protocol, which should be used for calculating emissions factors for these types of systems once it has been completed.

Applying GHG Factors to the Building

The GHG emission factors must be applied to the Energy and Thermal Load outputs of the Proposed Building energy assessment as follows:

- Electricity demand: The overall blended GHG factor for electricity supplied to the building for electrical demands within the building.
- Thermal energy: The overall GHG factors for chilled water, heating hot water and domestic hot water should be applied to the *heat and cooling loads* for the Proposed Building.

The grid GHG factors must be applied to the Reference Building and the Intermediate Building. The final GHG emissions for the Proposed Building will be compared to the GHG emissions of the Reference Building to determine the number of points awarded for the credit.

NABERS Energy and the Energy Efficiency Council Approach

The Energy Efficiency Council is preparing an Emissions Allocation Protocol, which should be used for calculating emissions factors for these types of systems once it has been completed. Feedback from the EEC is that the current NABERS Energy approach will likely be adopted.

The NABERS Energy approach is similar to that described above, but is only applicable to co- and trigeneration systems; it also cannot be used where electricity is transferred via the grid. Buildings seeking certification using the *NCC Class* 5 - Office DTS Pathway that are served by just co- or trigeneration systems may use the NABERS Energy protocol and calculator to assess the energy inputs attributable to the building.

Green Star – Design & As Built Shared Services and Low-Carbon Energy Supply Assessment Guidelines

DRAFT d1

A simple calculator has been produced for assessing these systems with total emissions allocation as the output. This calculator must be completed by the project seeking certification with contractual documentation evidence demonstrating that the inputs and outputs are accurately represented.

3. Documentation

Beyond the standard design and construction documentation for the building, the following additional documentation is required for shared energy systems:

Procurement Contractor Approach

 Power Purchase Agreement (PPA) and Thermal Power Purchase Agreements for *three years* after practical completion identifying supply availability and Guaranteed GHG emission factor.

Design Analysis Approach

- Design Intent Report (DIR) for the utility identifying its characteristics and associated GHG coefficient calculations.
- Power Purchase Agreement (PPA) and Thermal Power Purchase Agreements for *three years* after practical completion identifying supply availability and an operational plan which corresponds with the DIR.

Design and construction documentation for the energy utility are *not* required for the purposes of the Green Star submission for the buildings.

Step 1: Defining the utility

The utility is a district thermal system including a tri-generation process distributing electricity, heating hot water, chilled water and domestic hot water.

Inputs:

- Fuel for generation
- Grid energy for mechanical chillers
- Grid energy for small power

Outputs:

- Electricity
- Chilled Water (CHW)
- Heating hot Water (HHW)
- Domestic Hot Water (DHW)

By-products:

- GHG Emissions
- Waste heat

AIR TO WATER HEX ON EXHAUST GAS FLUE AND JACKET WATER COUPLED TO A COMMOM HOT WATER CIRCUIT PIPED TO ABSORBTION CHILLER.

Step 2: Calculating GHG Emission Factors

Green Star - Design & As Built April 2014, DRAFT d1

*The GHG emissions must be split proportionally between usable energy streams, requiring consideration in the same units.

**The natural gas and electricity GHG factors used must be the applicable state/territory values as per the Green Star Energy Calculator.

Step 2: Calculating GHG Emission Factors

Chilled Water (15%*)

kgCO_{2CHW} = CHW Proportion (output) / Usable Energy Input x Total GHG

> *The GHG emissions must be split proportionally between energy streams, requiring consideration in the same units.

Step 2: Calculating GHG Emission Factors

Step 3: Applying GHG Emission Factors

April 2014, DRAFT d1
